The novel coronavirus disease 2019 (COVID-19) pandemic is challenging health care systems worldwide and raising important ethical issues, especially regarding the potential need for rationing health care in the context of scarce resources and crisis capacity. Even if capacity to provide care is sufficient, one priority should be addressing goals of care in the setting of acute life-threatening illness, especially for patients with chronic, life-limiting disease.

Clinicians should ensure patients receive the care they want, aligning the care that is delivered with patients’ values and goals. The importance of goal-concordant care is not new or even substantially different in the context of this pandemic, but the importance of providing goal-concordant care is now heightened in several ways. Patients most likely to develop severe illness will be older and have greater burden of chronic illness—exactly those who may wish to forgo prolonged life support and who may find their quality of life unacceptable after prolonged life support. In addition, recent reports suggest that survival may be substantially lower when acute respiratory distress syndrome is associated with COVID-19 vs when it is associated with other etiologies.

In this context, advance care planning prior to serious acute illness and discussions about goals of care at the onset of serious acute illness should be a high priority for 3 reasons. First, clinicians should always strive to avoid intensive life-sustaining treatments when unwanted by patients. Second, avoiding nonbeneficial or unwanted high-intensity care becomes especially important in times of stress on health care capacity. Third, provision of nonbeneficial or unwanted high-intensity care may put other patients, family members, and health care workers at higher risk of transmission of severe acute respiratory syndrome coronavirus 2. Now is the time to implement advance care planning to ensure patients do not receive care they would not want if they become too severely ill to make their own decisions. As eloquently pointed out by an intensivist, “If you do not talk with [your family] about this now, you may have to have a much more difficult conversation with me later.” Several online resources can guide these advance care planning discussions.

For patients in a community setting or living in a nursing home, clinicians should engage in discussions about goals of care now, especially with older patients with chronic disease. During this pandemic when nonessential medical visits are currently limited, these conversations may need to occur via telemedicine (either as a stand-alone appointment or in combination with an appointment designated or scheduled for another purpose). This process should include primary care and specialty clinicians (eg, cardiologists, pulmonologists, nephrologists, oncologists, and geriatricians), and patients might appreciate this opportunity to discuss advance care planning. Depending on state regulations, patients with chronic life-limiting illness should be offered the option to complete a physician order for life-sustaining treatments form, especially if they would not want to receive cardiopulmonary resuscitation (CPR) or mechanical ventilation.

For hospitalized patients, one focal point for goal-concordant care is related to discussions of code status or the use of CPR and advanced cardiac life support (ACLS). Many hospital-based clinicians over-emphasize code status as the first step of a goals-of-care discussion, but asking patients about CPR before assessing values and goals leads to ineffective code status discussions. During this pandemic, it is equally important to understand a patient’s values and goals prior to discussing code status; however, the importance of avoiding inappropriate CPR has increased for 2 reasons. One reason is that although unwanted or nonbeneficial CPR under any circumstance may risk increasing psychological distress for patients’ family members, inappropriate CPR during the pandemic is especially stressful and potentially dangerous for health care workers. Another reason is that nonbeneficial or unwanted ACLS will strain available resources for personal protective equipment because multiple health care workers are needed for effective ACLS. Therefore, the COVID-19 pandemic heightens the importance of implementing do-not-resuscitate (DNR) orders for appropriate hospitalized patients.

The implementation of DNR orders can occur in 3 situations. First, patients or their surrogate decision makers may clearly understand and communicate that the patient would not want CPR if the heart were to stop and may even have a physician’s order for life-sustaining treatments form that specifies such. Second, patients or their surrogate decision makers may follow the recommendation of a clinician to forgo CPR; this may occur through informed consent or, occasionally, informed assent (as discussed below). Third, in extreme situations in which CPR cannot possibly be effective, clinicians in some health care settings may unilaterally decide to write a DNR order. This latter approach is not uniformly accepted and, prior to COVID-19, it rarely had a role. During this pandemic, however, in extreme situations such as a patient with severe underlying chronic illness and...
Is longevity the patient’s primary value above all else, including quality of life?

Proceed with informed assent

Informed assent not appropriate

1. Assess patient’s values and goals
   - Elicit values and preferences for therapies and outcomes from the patient or designated family member and formulate overall therapeutic goals
   - "Is it important to your mother to live as long as possible, no matter what her quality of life, or are there circumstances in which she would not want to receive life support, such as a prolonged nursing home stay?"

2. Discuss cardiopulmonary resuscitation (CPR)
   - Briefly describe CPR explaining how, when, and why it is performed
   - "We want to be sure we are taking the best possible care of your mother, so I would like to talk to you about CPR."

3. Summarize the role of CPR
   - Provide a personalized explanation about the lack of ability of CPR to achieve the previously assessed patient goals
   - "Given what you have told me about your mother and her goals, CPR will not help her reach her goals."

4. Present a definitive assent statement
   - Inform the patient or the patient’s family that CPR will not be offered
   - "Since CPR will not work to achieve your mother’s goals in this situation, we do not provide it."

5. Assess understanding and allow for objection
   - Discuss the patient’s or family’s understanding of the assent statement, the decisions made, and any objections they may have
   - "I want to make sure you understand. Do you have any questions?"

Figure. Proposed Components of Informed Assent Framework

Role of the Funder/Sponsor:

Dr Curtis reports receipt of grants from NIH and from Cambia Health Foundation. Dr Fausto reports receipt of grants from NIH outside the submitted work. Dr Stapleton reports receipt of grants from NIH and the National Institute on Aging outside the submitted work.

Conflict of Interest Disclosures: Dr Curtis reports receipt of grants from the National Institutes of Health (NIH) and from Cambia Health Foundation. Dr Kross reports receipt of grants from NIH outside the submitted work. Dr Stapleton reports receipt of grants from NIH and the National Institute on Aging outside the submitted work.

Role of the Funder/Sponsor: None of the funders had a role in the preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication.

Additional Contributions: The authors would like to thank Anthony L. Back, MD, Ruth A. Engberg, PhD, James Fausto, MD, eMHA; Dee Ford, MC, MSCR; and Christine Ritchie MD, MSPH, for their contributions to the practical steps for informed assent.
